Hiperparameters setting - Deflected Subgradient

Final Model

Learning Algorithm	#Units, lambda, beta, delta, R, rho	RMSE(TR/VL/TS)
Stepsize-restricted	h1=30, h2=20, λ=1e-4, β=0.3, δ=0.1, R=0.1, ρ=0.7	0.5415/0.6737/0.7087

Some results abouts hyperparameters for Deflected Subgradient

Red curve: Validation **Blue curve: Training**

h1=40, h2=30, λ=5e-5, β=0.07, δ=0.07, R=0.1, ρ=0.7

Lower values of **β** and **δ** were tested compared to the final model. As observed from both the training and validation RMSE, the model performs significantly worse (approximately 5 percentage points lower), due to a too slow descent, which triggers early stopping before full convergence. This behavior was observed in the majority of models tested with **β** and **δ** values lower than those of the final model.

h1=50, h2=40, λ=5e-5, β=0.5, δ=0.05, R=1, ρ=0.7

In this case, however, higher values of the hyperparameters **R** and **β** were tested in an attempt to speed up convergence. As seen from the validation curve, these overly aggressive values lead to overfitting.

h1=30, h2=30, λ=1e-7, β=0.1, δ=0.5, R=1, ρ=0.7

These unsmooth curves are caused by a too low **λ** value combined with an overly aggressive **δ** in the *f** update.

h1=30, h2=20, λ=1e-3, β=0.2, δ=0.01, R=0.3, ρ=0.3

In this model, we tested lower values of **δ** and **ρ** to reduce the step size and potentially improve validation performance. However, the learning curve again exhibited slow convergence, without any noticeable improvement in results.

h1=60, h2=60, λ=1e-7, β=0.3, δ=0.1, R=0.1, ρ=0.7

Finally, by increasing the number of neurons while keeping the other hyperparameters at the levels of the best model, we observed irregular behavior:

some folds terminated very early, while others reached slightly better convergence than the final model, but with irregular, unsmooth learning curves.
